

# The FRMS scenario implications on present day globular clusters

**William Chantereau**

**Corinne Charbonnel**

**Thibaut Decressin**

**Georges Meynet**

# Outline

- Fast Rotating Massive Star scenario
- 2G star behaviour
- Implications on the globular clusters' star distribution

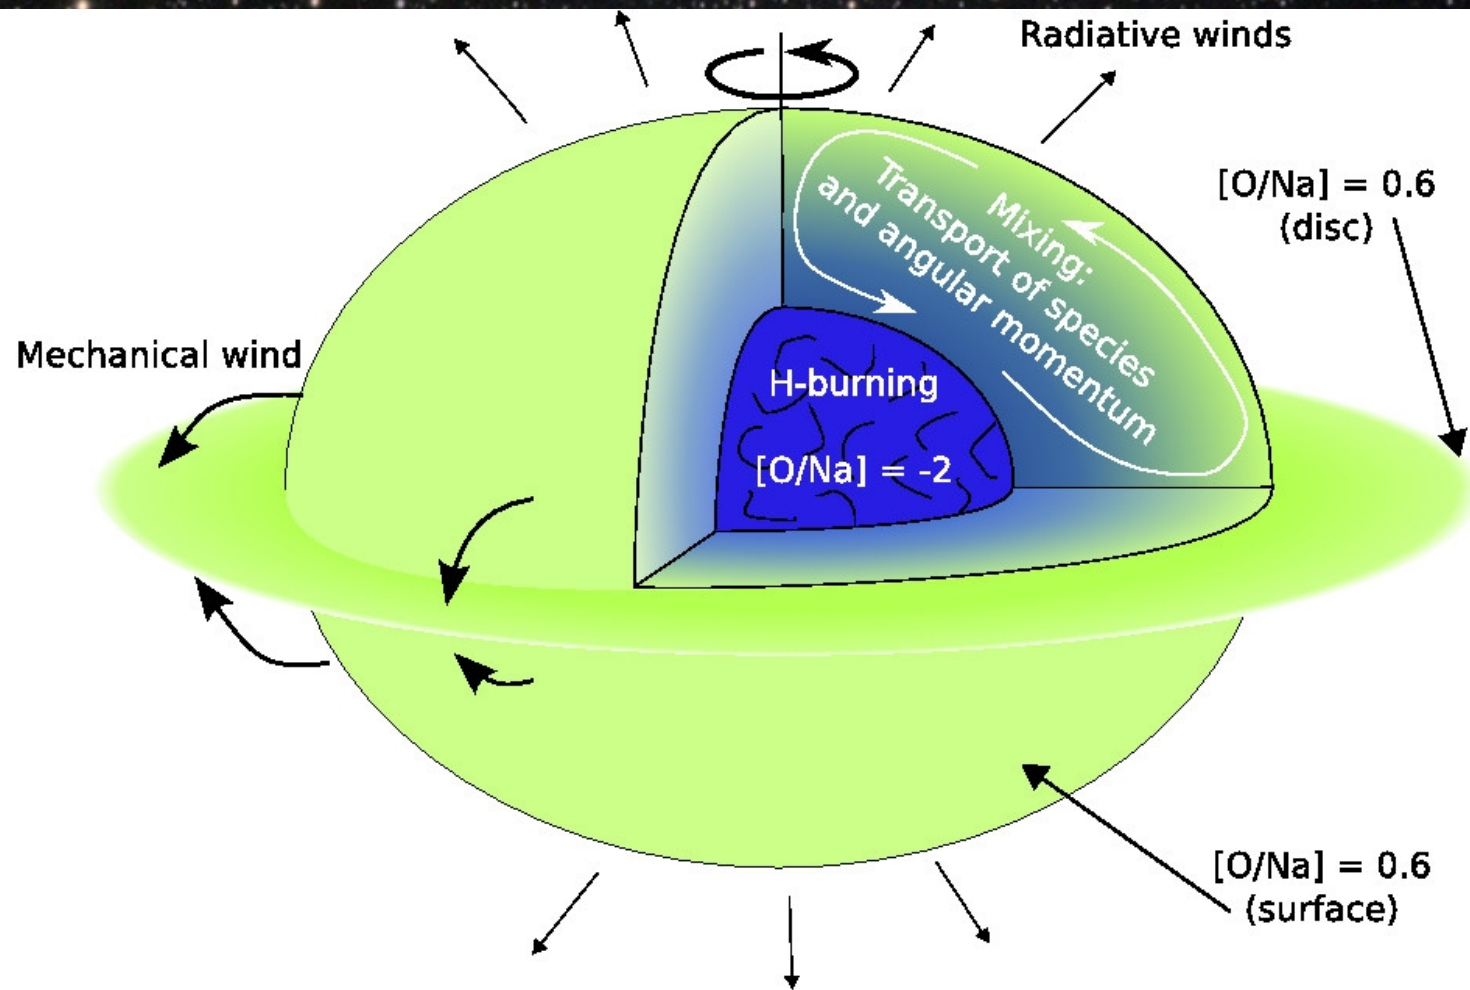

# Fast Rotating Massive Stars (FRMS) scenario (Decressin et al. 2007b)

- Mass  $> 25 M_{\text{sun}}$
- H-burning products at very high temperature in the central parts during the main sequence
- Chemical elements transported to the surface through the rotationnal mixing
- Slow mechanical and equatorial wind
- Helium content of the ejecta from 0.248 to a value higher than 0.4

# FRMS scenario (Decressin et al. 2007b)

# FRMS scenario (Decressin et al. 2007b)

# FRMS scenario (Decressin et al. 2007b)

# Initial He distribution for the 2G stars from the FRMS scenario

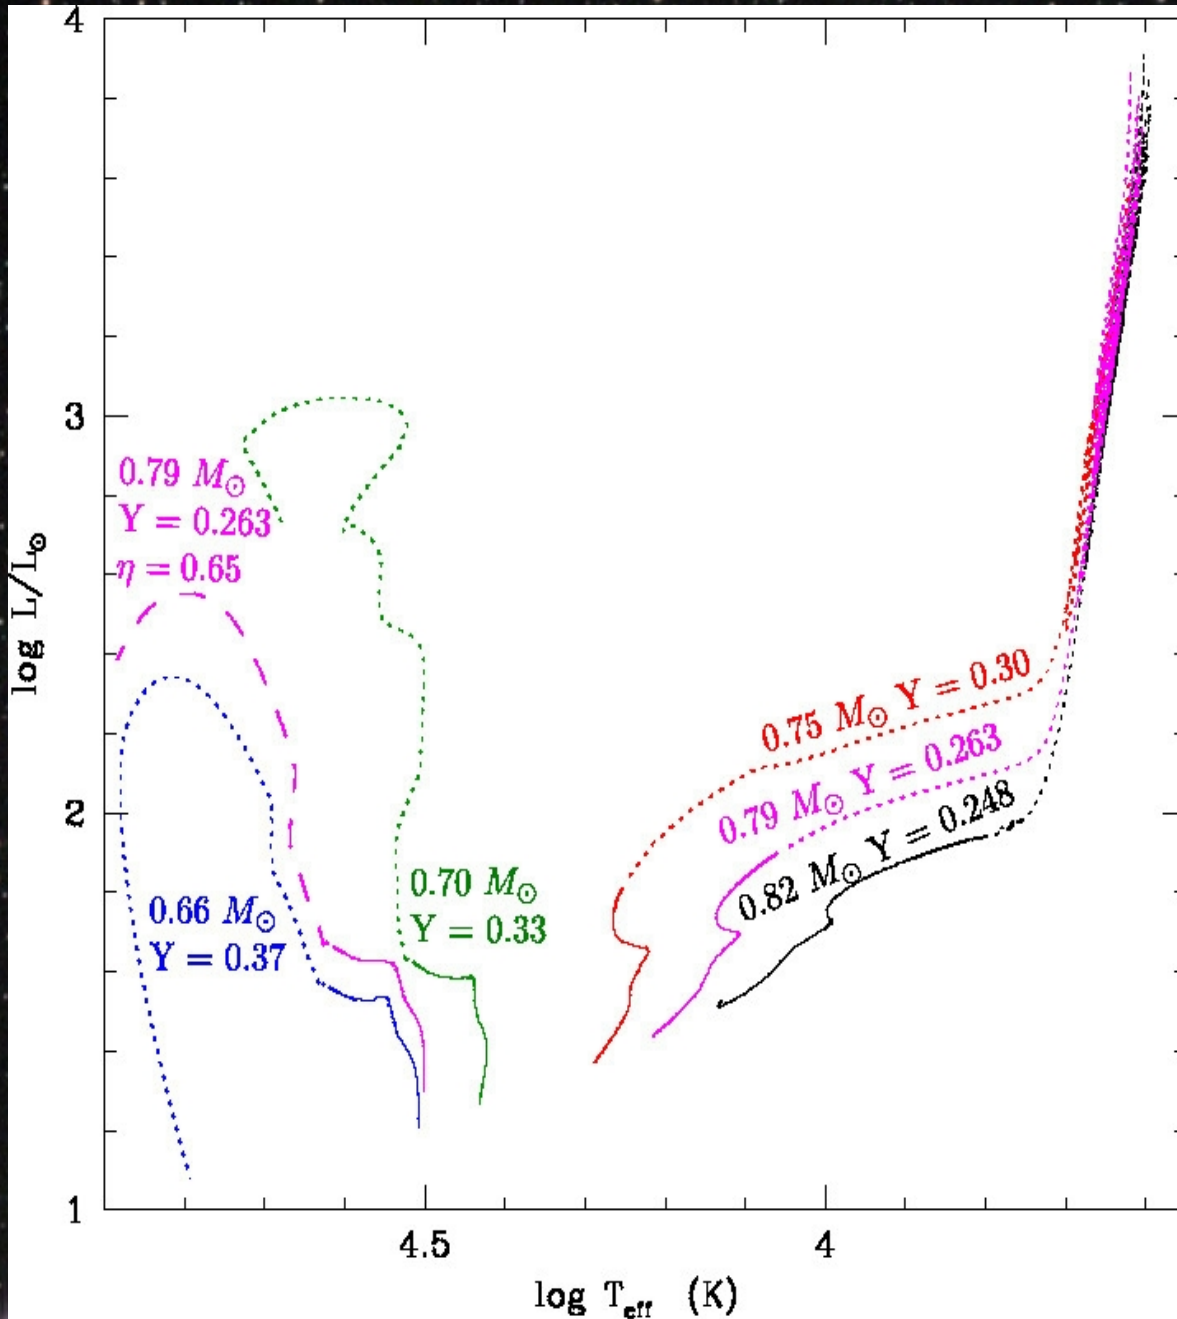

- Around 7 % of the stars with an initial He above 0.4 and up to 0.8

- Greater mean molecular weight and lower opacity because of the He content
- Shift to the bluer and higher L part of the HRD

Peculiar  
well-known  
behaviour :

Late hot flasher  
and  
AGB-manqué

(Charbonnel et al.  
2013)

Suitable  
explanation for  
the lack of  
sodium-rich  
stars on the  
AGB

# Fate and age of the 2G stars

Age at the end of the HB or at the RGB tip for stars ending as He WD.

(Charbonnel et al. 2013)

# Conclusion

- Low proportion of « super He-rich stars » at the birth of the second generation
- Suitable explanation for the absence of sodium-rich stars on the AGB
- No super He-rich stars on the HB and AGB and very difficult to observe on the MS and RGB

The background of the entire slide is a deep black space filled with numerous stars of varying brightness and colors, including white, yellow, and blue. The stars are distributed across the entire frame, creating a sense of depth and vastness.

# Thank you
